- 4 Other algorithms
- 5 Quicksort
 - Divide & Conquer
- 6 Comparing
- 7 Recap

Sorting is one of the classic problems for learning algorithms.

- Requirement for everything.
- Obvious applications like sorting text, statistics (median calculations).
- Less obvious, sorting objects in games for FOV calculations.
- Route planning.

Very simple sort.

- Compares each item to the next in the sequence.
- Swap items if in wrong order.

Iterating over the sequence once isn't typically enough.

- Keep iterating over the sequence until elements are sorted.

Bubble sort is what's known as an stable in-place sort.

Stable meaning that equivalent elements do not change their relative orders.

- Not important if e.g. sorting people by height.
- Important if e.g. priority queues.
 - Imagine a queue in an emergency room.
 - Treat the most serious conditions first, sort people on how bad injury is.
 - If many people have same injury then should be seen based on when entered queue.

With unstable sorting algorithm the relative orders of equivalent elements can be changed.

In-place meaning that it only needs a small amount of additional memory in order to work.

- More memory efficient than the alternative.
- Can be important if...
 - ...dealing with large amounts of data.
 - ...have limited resources (i.e. embedded systems).
- Bubble sort only needs a few extra variables to swap the elements and to step through the sequence.

One of the simplest sorting algorithms.

- Explained here to introduce you to sorting concepts.
 - In-place, stable.
- Is rubbish.
 - Horrible performance, average is $O(n^2)$.
 - But best case is only $O(n)$.

The time taken to sort a sequence depends on:

- The starting order of the sequence.

For example, Bubblesorting a 100 elements:

- Best case, are already sorted.
 - Iterate over sequence once.
 - 100 comparisons.
- Worst case, in reverse order.
 - Iterate over sequence 100 times.
 - 10,000 comparisons.
- Average case, random order.
 - Somewhere in between.

So sorting algorithms have 3 $O()$ values.

- Divides sequence into sorted and unsorted regions.
 - Not stable.
 - In place.
- 1 Iterate over sequence.
 - 2 For each element search the remaining elements on its right for the smallest value.
 - 3 Swap smallest element with current element.

- 1 Iterate over sequence.
- 2 For each element search the remaining elements on its right for the smallest value.
- 3 Swap smallest element with current element.

Selection sort II

C

Bubblesort is $O(n^2)$.

Selection sort is $O(n^2)$.

- Selection sort is generally faster than bubble.
 - But have same $O()$ complexity.
 - WTF?
- $O()$ notation describes how an algorithm will grow.
- Not good at absolute performances.
- Selection sort typically does fewer comparisons and swaps than bubblesort.
 - Therefore faster.

Sorting Algorithms

Many sorting algorithms

- Different trade-offs, performances. <https://www.youtube.com/watch?v=ZZuD6iUe3Pc>
- Some are just jokes.

- | | | | | | |
|---|----------|----|-------------|----|-----------|
| 1 | Bead | 9 | Gnome | 17 | Radix |
| 2 | Bogo | 10 | Heap | 18 | Selection |
| 3 | Bubble | 11 | Insert | 19 | Shell |
| 4 | Circle | 12 | Merge | 20 | Sleep |
| 5 | Cocktail | 13 | Pancake | 21 | Stooge |
| 6 | Comb | 14 | Patience | 22 | Strand |
| 7 | Counting | 15 | Permutation | 23 | Tree |
| 8 | Cycle | 16 | Quick | | |

Neither bubble or selection sort are very good.

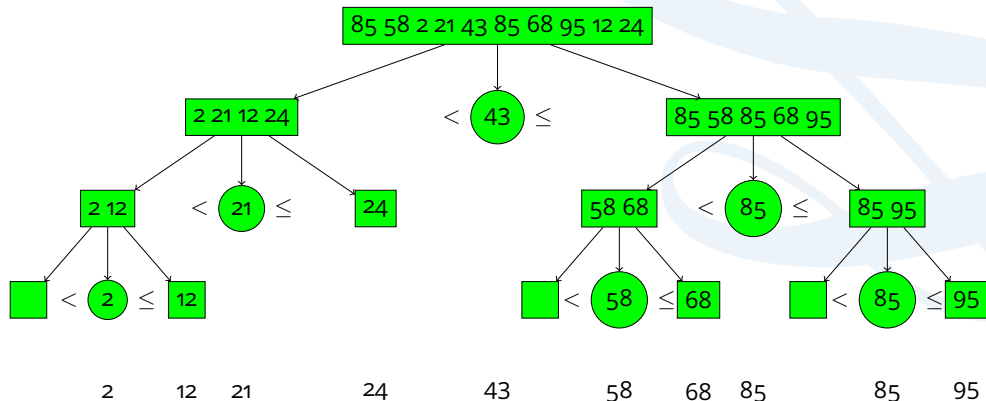

- Simple algorithms but slow.
- Not used in real life.

One of the fastest sorting algorithms.

- Used in real life.
- Recursively breaks the sequence in half.
 - Divide & Conquer.

- 1 Select a value from the sequence, this is the pivot.
- 2 Put all values $<$ pivot in one group.
- 3 Put all values $>$ pivot in another group.
- 4 Treat each group as a new sequence and repeat from step 1.

- 1 Select a value from the sequence, this is the pivot.
- 2 Put all values $<$ pivot in one group.
- 3 Put all values $>$ pivot in another group.
- 4 Treat each group as a new sequence and repeat from step 1.

Quicksort is...

- ...sometimes in-place.
 - Depends on implementation.
- ...sometimes stable.
 - Depends on implementation.

Some issues with the original algorithms (1959).

- Choosing the pivot.
 - First element.
 - Middle element.
 - Average of first, middle and last.
- Repeated elements.
 - Fat partition.

Divide and Conquer

C

Quicksort is a divide and conquer algorithm.

- Too hard to sort the whole sequence?
- Divide the problem.
 - Still too hard?
 - Divide the problem.
 - Still too hard?
 - Divide the problem.
 - Etc, etc, etc.

Naturally suited for parallelism.

Have seen there are many ways to sort.

- Best sorting algorithm depends on multiple factors.
- Good in one situation is bad in another.

- Stability? In place?

- What are you sorting?

- Linked lists?

- Sequential memory (arrays)?

- Where are you sorting?

- RAM?

- EEPROM? cheap to read, expensive to write.

- Size of n .

- Insertion sort with small n .

- Consistent performance.

- Selection sort.
